Compare and Contrast
Many ideas in this lesson are connected because they explain comparisons and contrasts-how things are alike and different. Active readers stay focused on comparisons and contrasts when they ask themselves, How are these things alike?
How are they different?

## Solar System

The sun, Earth, and its
moon form a system in space.
Earth revolves around the sun.
That means Earth travels around
the sun in a path called an orbit. The moon revolves around Earth. Read on to learn about other objects in space. ACTIVE READING As you read this page, underline two details that tell how all planets are alike.

Earth and its moon are part of a larger system in space called a solar system. A solar system is made up of a star and the planets and other space objects that revolve around it. A planet is a large, round body that revolves around a star. In our solar system, the planets and other objects revolve around a star we call the sun.

There are eight planets in our solar system. All of them rotate, or spin, about an axis. This is an imaginary line that goes through the center of a planet. Earth rotates on its axis once every 24 hours. This is the length of one day on Earth.

Unlike planets, some objects don't revolve directly around the sun. Moons are small natural objects that revolve around other objects. Many planets have moons. Earth has only one. It revolves once around Earth about every 27 days.

Earth is about 150 million kilometers from the sun!

The planets in our solar system are very far from each other.

The orbits of the planets in our solar system are not perfect circles. They are oval-shaped, or elliptical [eh•LIP॰tuh॰kuhl].

## Around and Around

Draw an orbit for the planet. Then draw a moon and its orbit.

Some planets have many moons. Earth has only one. Venus and Mercury have none!
planet
-

## The Ther Planets

At times, the brightest object in the night sky is not the moon or a star. It is Venus, one of

- Earth's closest neighbors in space.

ACTIVE READING As yoû read this page, underline

## Mercury

Mercury, the smallest planet in our solar system, is less than half the size of Earth. Its surface is filled with craters, much like Earth's moon. Mercury is the closest planet to the sun. On Mercury, the sun would look three times as large as it does on Earth.

## Venus

Venus is so hot that lead would melt at its surface! Thick clouds surround Venus, and its atmosphere is made up mostly of carbon dioxide.
Lava flows from more than 1,000 volcanoes on Venus's surface.

Planets in our solar system can be classified based on their distance from the sun. The four inner planets are the closest to the sun. In order from closest to farthest, the inner planets are Mercury, Venus, Earth, and Mars.

The inner planets are very dense and rocky. They have thin atmospheres and small diameters. A planet's diameter is the distance from one side of the planet, through its center, to the other side. The inner planets have large solid cores at their centers. They have few moons, and their revolution times are short compared to the other planets in the solar system.

## Earth

Earth is the third planet from the sun. It has an atmosphere made of mostly nitrogen, oxygen, and carbon dioxide. Earth is the only planet known to have abundant liquid water, which helps to keep Earth at temperatures that allow life.

## No Home for Me

List three reasons why people could not live on Venus.

1. $\qquad$ Mars
2. $\qquad$
Sometimes you can see Mars in the night sky. Mars is known as the "Red Planet" because of its red, rocky surface. Giant dust storms often cover the entire planet, forming huge sand dunes. Mars, like the other inner planets, has many volcanoes.

## Outer Planets

On a clear night, Jupiter might appear to be a large, bright star in the night sky. But in fact, Jupiter is one of the outer planets in our solar system.

Great Red Spot

ACTIVE READINS As you read this page, underline ways in which the outer planets are alike.

## O Jupiter

Jupiter is the largest planet in the solar system. In fact, all of the other planets would fit inside Jupiter! Its Great Red Spot is about as wide as three Earths. The red spots are massive, spinning storms. Jupiter's faint rings were discovered by the Voyager 1 space probe in 1979.

Jupiter, Saturn, Uranus, and Neptune are the outer planets. In that order, they are the farthest planets from the sun. The outer planets are also called the gas giants, because they are huge and made up mostly of gases. They don't have a solid surface, and their cores are very small.

Because the gas giants are so far away from the sun, their surfaces are much colder than the inner planets. All of the outer planets have many moons and ring systems. Saturn's ring system is more visible than those of the other outer planets.

## Saturn

Saturn, the second largest planet, has thousands of rings around it. The rings are made up of ice and chunks of rock. Some of Saturn's moons are found inside these rings. Like Jupiter, Saturn has large storms.

# What Makes Them Unique? 

 Write one thing that is unique about each of the outer planets.
## Jupiter

## Uranus

## Neptune

## Uranus

The axis of Uranus is tilted so far that, compared to other planets, it rotates on its side. This makes seasons on Uranus last more than 20 years! Deep inside Uranus, heated gases bubble and burst onto the surface, causing bright clouds to form. Uranus has a system of at least 13 faint rings.

## Neptune

Neptune is the windiest planet in our solar system. Its winds move at speeds of about 2,000 km/hr (1,243 mi/hr). These winds blow Neptune's Great Dark Spot around the planet. This spot is a storm, about the size of Earth, known to vanish and reform! Neptune has nine rings around it.

# Compare Inner and Outer Planets 

Size, surface features, and distance from the sun are just some differences between the inner and outer planets.
Look at this chart to learn about other differences.

| Planet | Period of Revolution <br> (in Earth days and years) | Period of Rotation <br> (in Earth hours and days) | Temperature <br> $\left({ }^{\circ} \mathrm{C}\right)$ (inner planets: surface range; outer planets: top of the clouds) | Number of Moons | Density (g/cm ${ }^{3}$ ) | Diameter |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| INNER PLANETS |  |  |  |  |  |  |
| Mercury | 88 days | 59 days | -173 to 427 | 0 | 5.43 | $\begin{array}{\|l} 4,878 \mathrm{~km} \\ (3,031 \mathrm{mi}) \end{array}$ |
| Venus | 225 days | 243 days | 462 | 0 | 5.24 | $\begin{aligned} & 12,104 \mathrm{~km} \\ & (7,521 \mathrm{mi}) \end{aligned}$ |
| Earth | 365 days | 1 day | -88 to 58 | 1 | 5.52 | $\begin{aligned} & 12,756 \mathrm{~km} \\ & (7,926 \mathrm{mi}) \end{aligned}$ |
| Mars | 687 days | about 1 day | -87 to -5 | 2 | 3.94 | $\begin{aligned} & 6,794 \mathrm{~km} \\ & (4,222 \mathrm{mi}) \end{aligned}$ |
| OUTER PLANETS |  |  |  |  |  |  |
| Jupiter | 12 years | about 10 hours | -148 | 67 | 1.33 | $\begin{aligned} & 142,984 \mathrm{~km} \\ & (88,846 \mathrm{mi}) \end{aligned}$ |
| Saturn | 29 years | about 10 hours | -178 | 62 | 0.70 | $\begin{aligned} & 120,536 \mathrm{~km} \\ & (74,898 \mathrm{mi}) \end{aligned}$ |
| Uranus | 84 years | about 17 hours | -216 | 27 | 1.30 | $\begin{aligned} & 51,118 \mathrm{~km} \\ & (31,763 \mathrm{mi}) \end{aligned}$ |
| Neptune | 165 years | about 16 hours | -214 | 14 | 1.76 | $\begin{aligned} & 49,528 \mathrm{~km} \\ & (30,775 \mathrm{mi}) \end{aligned}$ |

## 

Find an Average
In the space below, find the average density of the four inner planets. Repeat for the four outer planets. Inner planets:

Outer planets:

How do the average densities compare?

The density of water is 1 gram per cubic centimeter ( $\mathrm{g} / \mathrm{cm}^{3}$ ). Saturn would float because its density is less than the density of water. Earth would sink.

## Patterns in Data

Look at the data table on the previous page. Describe two trends in the data between the inner and outer planets.
$\qquad$
$\qquad$
$\qquad$
$\qquad$

## The Flying

## Moons

Besides planets, there are many other bodies that orbit the sun. Let's find out more about some of them.

ACTIVE READING As you read these two pages, find and underline two fácts about asteroids. ${ }^{\text {. }}$

## Dwarf Planets

Pluto was once called a planet. But in 2006, it was reclassified as a dwarf planet. Dwarf planets are nearly round bodies whose orbits cross the orbits of other bodies. Most are found in a region of the solar system beyond Neptune's orbit called the Kuiper belt. These objects are far away and hard to study. Quaoar, shown above, was discovered in 2002.

Other moons are very different from Earth's moon. Europa, one of Jupiter's moons, may have a liquid ocean under a layer of ice. Another of Jupiter's moons, lo [EYE•oh], has the most active volcanoes of any body in the solar system.

Asteroids

Asteroids are rock and iron objects that orbit the sun. Millions of them are found in the wide region between Mars and Jupiter known as the asteroid belt. Some asteroids are as small as a city block. Others could fill up an ocean. Some asteroids even have their own moons!

## Meteoroids, Meteors, and Meteorites

Each day, tons of meteoroids hit Earth's atmosphere. Meteoroids are pieces of rock that break off of asteroids and travel through space. Most meteoroids burn up in Earth's atmosphere, causing a streak of light called a meteor. Meteoroids that reach Earth's surface are called meteorites.

## Comets

A comet is a chunk of frozen gases, rock, ice, and dust. Comets have long orbits around the sun. As comets pass close to the sun, part of their frozen surface begins to break away and turn into gases and dust. These particles reflect the sun's light and become visible as long tails. A comet's tails always point away from the sun.

## Space Natch

Some objects in space cross each others' orbits.
Often, nothing happens. But sometimes the objects hit each other. Scientists look out for objects that may cross Earth's orbit.

Pictures of the surface of the moon tell a story. Over millions of years, space objects such as comets, meteoroids, and asteroids have impacted, or hit, the moon. Impact craters of all sizes can be found on the moon's surface.

Space objects have also hit other bodies in the solar system. A comet named ShoemakerLevy 9 impacted Jupiter in 1994. Pictures of the impact were taken by the Galileo space probe.

Scientists know that large objects have also hit Earth. In fact, a huge one impacted Earth about 65 million years ago. Many scientists think it caused changes in the environment that killed all the dinosaurs. Luckily, impacts like that one do not happen often.

Scientists use telescopes to scan space for near-Earth asteroids. These are objects that may cross Earth's orbit. Scientists keep track of their size, position, and motion. They analyze this data to determine if the objects could impact Earth.

The impact of Shoemaker-Levy 9 caused bubbles of hot gas to rise into Jupiter's atmosphere, as well as dark spots to form on its surface.
